

HIGHLIGHTS OF PRESCRIBING INFORMATION

These highlights do not include all the information needed to use DAPTOMYCIN for injection safely and effectively. See full prescribing information for DAPTOMYCIN for injection.

DAPTOMYCIN for injection for intravenous use Initial U.S. Approval: 2003

Table with 2 columns: RECENT MAJOR CHANGES and Dosage and Administration (2.5). Includes Indications and Usage (2.1) and Dosage and Administration (2.2).

Table with 3 columns: Creatinine Clearance (CLcr), Dosage Regimen, and S. aureus Bloodstream Infections. Shows dosing for cSSSI and S. aureus Bloodstream Infections based on CLcr.

Administered following hemodialysis on hemodialysis days. Administered intravenously in 0.9% sodium chloride, either by injection over a 2-minute period or by infusion over a 30-minute period.

500 mg lyophilized cake or powder for reconstitution in a single-dose vial (3). Known hypersensitivity to daptomycin (4).

Warnings and Precautions (5.1) Anaphylaxis/hypersensitivity reactions (including life-threatening); Discontinue Daptomycin for Injection and treat signs/symptoms. (5.1)

Adverse Reactions (6.1) The most clinically significant adverse reactions observed with Daptomycin for Injection 4 mg/kg (cSSSI trials) and 6 mg/kg (S. aureus bacteremia/endocarditis trial) were abnormal liver function tests, elevated CPK and dyspnea. (6.1)

To report SUSPECTED ADVERSE REACTIONS, contact Hospira, Inc. at 1-800-441-4100, or FDA at 1-800-FDA-1088 or www.fda.gov/medwatch.

See 17 for PATIENT COUNSELING INFORMATION. Revised: 9/2016

FULL PRESCRIBING INFORMATION: CONTENTS*

Table listing sections 1 through 17: INDICATIONS AND USAGE, DOSAGE AND ADMINISTRATION, CONTRAINDICATIONS, WARNINGS AND PRECAUTIONS, ADVERSE REACTIONS, etc.

FULL PRESCRIBING INFORMATION

1 INDICATIONS AND USAGE Daptomycin for Injection is indicated for the treatment of the infections listed below.

1.1 Complicated Skin and Skin Structure Infections Complicated skin and skin structure infections (cSSSI) caused by susceptible isolates of the following Gram-positive bacteria: Staphylococcus aureus (including methicillin-resistant isolates), Streptococcus pyogenes, Streptococcus agalactiae, Streptococcus dysgalactiae subsp. equisimilis, and Enterococcus faecalis (vancomycin-susceptible isolates only).

1.2 Staphylococcus aureus Bloodstream Infections (Bacteremia), Including Those with Right-Sided Infective Endocarditis, Caused by Methicillin-Susceptible and Methicillin-Resistant Isolates Staphylococcus aureus bloodstream infections (bacteremia), including those with right-sided infective endocarditis, caused by methicillin-susceptible and methicillin-resistant isolates.

2 DOSAGE AND ADMINISTRATION 2.1 Administration Duration Daptomycin for Injection should be administered intravenously either by injection over a two (2) minute period or by infusion over a thirty (30) minute period.

2.2 Complicated Skin and Skin Structure Infections Daptomycin for Injection 4 mg/kg should be administered intravenously in 0.9% sodium chloride injection once every 24 hours for 7 to 14 days.

2.3 Staphylococcus aureus Bloodstream Infections (Bacteremia), Including Those with Right-Sided Infective Endocarditis, Caused by Methicillin-Susceptible and Methicillin-Resistant Isolates Daptomycin for Injection 6 mg/kg should be administered intravenously in 0.9% sodium chloride injection once every 24 hours for 2 to 6 weeks.

Table 1. Recommended Dosage of Daptomycin for Injection in Adult Patients

Table with 3 columns: Creatinine Clearance (CLcr), Dosage Regimen, and S. aureus Bloodstream Infections. Shows dosing for cSSSI and S. aureus Bloodstream Infections based on CLcr.

* When possible, administer Daptomycin for Injection following the completion of hemodialysis on hemodialysis days.

2.5 Preparation of Daptomycin for Injection for Administration

Reconstitution of Daptomycin for Injection Vial Daptomycin for Injection is supplied in single-dose vials, each containing 500 mg daptomycin as a sterile, lyophilized cake or powder. The contents of a Daptomycin for Injection vial should be reconstituted, using aseptic technique, to 50 mg/mL as follows:

- 1. To minimize foaming, AVOID vigorous agitation or shaking of the vial during or after reconstitution.
2. Remove the polypropylene flip-off cap from the Daptomycin for Injection vial to expose the central portion of the rubber stopper.
3. Wipe the top of the rubber stopper with an alcohol swab or other antiseptic solution and allow to dry. After cleaning, do not touch the rubber stopper or allow it to touch any other surface.
4. Slowly transfer 10 mL of 0.9% sodium chloride injection through the center of the rubber stopper into the Daptomycin for Injection vial, pointing the transfer needle toward the wall of the vial. It is recommended that a beveled sterile transfer needle that is 21 gauge or smaller in diameter, or a needles device is used, pointing the transfer needle toward the wall of the vial.
5. Ensure that all of the Daptomycin for Injection cake or powder is wetted by gently rotating the vial.
a. Allow the wetted product to stand undisturbed for 10 minutes.
b. Gently rotate or swirl the vial contents for a few minutes, as needed, to obtain a completely reconstituted solution.

Administration Instructions

Parenteral drug products should be inspected visually for particulate matter prior to administration. Slowly remove reconstituted liquid containing daptomycin (50 mg/mL) from the vial using a beveled sterile needle that is 21 gauge or smaller in diameter. Administer as an intravenous injection or infusion as described below.

Intravenous Injection over a period of 2 minutes For intravenous (IV) injection over a period of 2 minutes, administer the appropriate volume of the reconstituted Daptomycin for Injection (concentration of 50 mg/mL).

Intravenous Infusion over a period of 30 minutes For IV infusion over a period of 30 minutes, the appropriate volume of the reconstituted Daptomycin for Injection (concentration of 50 mg/mL) should be further diluted, using aseptic technique, into a 50 mL IV infusion bag containing 0.9% sodium chloride injection.

No preservative or bacteriostatic agent is present in this product. Aseptic technique must be used in the preparation of final IV line. Do not exceed the In-Use storage conditions of the reconstituted and diluted solutions of Daptomycin for Injection described below. Discard unused portions of Daptomycin for Injection.

In-Use Storage Conditions for Daptomycin for Injection Once Reconstituted in Acceptable Intravenous Diluents Stability studies have shown that the reconstituted solution is stable in the vial for 12 hours at room temperature and up to 48 hours if stored under refrigeration at 2 to 8°C (36 to 46°F).

The diluted solution is stable in the infusion bag for 12 hours at room temperature and 48 hours if stored under refrigeration. The combined storage time (reconstituted solution in vial and diluted solution in infusion bag) should not exceed 12 hours at room temperature or 48 hours under refrigeration.

2.6 Compatible Intravenous Solutions Daptomycin for Injection is compatible with 0.9% sodium chloride injection and lactated Ringer's injection.

2.7 Incompatibilities Daptomycin for Injection is not compatible with dextrose-containing diluents. Daptomycin for Injection should not be used in conjunction with ReadyMED® elastomeric infusion pumps. Stability studies of Daptomycin for Injection solutions stored in ReadyMED® elastomeric infusion pumps identified an impurity (2-mercaptobenzothiazole) leaching from this pump system into the Daptomycin for Injection solution.

Because only limited data are available on the compatibility of Daptomycin for Injection with other IV substances, additives and other medications should not be added to Daptomycin for Injection single-dose vials or infusion bags, or infused simultaneously with Daptomycin for Injection through the same IV line. If the same IV line is used for sequential infusion of different drugs, the line should be flushed with a compatible intravenous solution before and after infusion with Daptomycin for Injection.

3 DOSAGE FORMS AND STRENGTHS 500 mg daptomycin as a sterile, pale yellow to light brown lyophilized cake or powder for reconstitution in a single-dose vial.

4 CONTRAINDICATIONS Daptomycin for Injection is contraindicated in patients with known hypersensitivity to daptomycin.

5 WARNINGS AND PRECAUTIONS 5.1 Anaphylaxis/Hypersensitivity Reactions Anaphylaxis/hypersensitivity reactions have been reported with the use of antibiatic agents, including Daptomycin for Injection, and may be life-threatening. If an allergic reaction to Daptomycin for Injection occurs, discontinue the drug and institute appropriate therapy [see Adverse Reactions (6.2)].

5.2 Myopathy and Rhabdomyolysis Myopathy, defined as muscle aching or muscle weakness in conjunction with increases in creatine phosphokinase (CPK) values to greater than 10 times the upper limit of normal (ULN), has been reported with the use of Daptomycin for Injection. Rhabdomyolysis, with or without acute renal failure, has been reported [see Adverse Reactions (6.2)].

Patients receiving Daptomycin for Injection should be monitored for the development of muscle pain or weakness, particularly of the distal extremities. In patients who receive Daptomycin for Injection, CPK levels should be monitored weekly, and more frequently in patients who received recent prior or concomitant therapy with an HMG-CoA reductase inhibitor or in whom elevations in CPK occur during treatment with Daptomycin for Injection.

In patients with renal impairment, both renal function and CPK should be monitored more frequently than once weekly [see Use in Specific Populations (8.6) and Clinical Pharmacology (12.3)]. In Phase 1 studies and Phase 2 clinical trials, CPK elevations appeared to be more frequent when Daptomycin for Injection was dosed more than once daily. Therefore, Daptomycin for Injection should not be dosed more frequently than once a day.

Daptomycin for Injection should be discontinued in patients with unexplained signs and symptoms of myopathy in conjunction with CPK elevations to levels >1,000 U/L (~5x ULN), and in patients without reported symptoms who have marked elevations in CPK, with levels >2,000 U/L (≥10x ULN). In addition, consideration should be given to suspending agents associated with rhabdomyolysis, such as HMG-CoA reductase inhibitors, temporarily in patients receiving Daptomycin for Injection [see Drug Interactions (7.1)].

5.3 Eosinophilic Pneumonia Eosinophilic pneumonia has been reported in patients receiving Daptomycin for Injection [see Adverse Reactions (6.2)]. It is reported as a non-infectious, self-limiting, acute lung disease characterized by fever, dyspnea with hypoxic respiratory insufficiency, and diffuse pulmonary infiltrates. In general, patients developed eosinophilic pneumonia 2 to 4 weeks after starting Daptomycin for Injection and improved when Daptomycin for Injection was discontinued and steroid therapy was initiated. Recurrence of eosinophilic pneumonia upon re-exposure has been reported. Patients who develop these signs and symptoms while receiving Daptomycin for Injection should undergo prompt medical evaluation, and Daptomycin for Injection should be discontinued immediately. Treatment with systemic steroids is recommended.

5.4 Peripheral Neuropathy Cases of peripheral neuropathy have been reported during the Daptomycin for Injection postmarketing experience [see Adverse Reactions (6.2)]. Therefore, physicians should be alert to signs and symptoms of peripheral neuropathy in patients receiving Daptomycin for Injection.

5.5 Potential Nervous System and/or Muscular System Effects in Pediatric Patients Younger than 12 Months Avoid use of Daptomycin for Injection in pediatric patients younger than 12 months due to the risk of potential effects on muscular, neuromuscular, and/or nervous systems (either peripheral and/or central) observed in neonatal dogs with intravenous daptomycin [see Nonclinical Toxicology (13.2)].

5.6 Clostridium difficile-Associated Diarrhea Clostridium difficile-associated diarrhea (CDAD) has been reported with the use of nearly all systemic antibiatic agents, including Daptomycin for Injection, and may range in severity from mild diarrhea to fatal colitis [see Adverse Reactions (6.2)]. Treatment with antibiatic agents alters the normal flora of the colon, leading to overgrowth of C. difficile. C. difficile produces toxins A and B, which contribute to the development of CDAD. Hypertoxin-producing strains of C. difficile cause increased morbidity and mortality, since these infections can be refractory to antimicrobial therapy and may require colectomy. CDAD must be considered in all patients who present with diarrhea following antibiatic use. Careful medical history is necessary because CDAD has been reported to occur more than 2 months after the administration of antibiatic agents.

If CDAD is suspected or confirmed, ongoing antibiatic use not directed against C. difficile may need to be discontinued. Appropriate fluid and electrolyte management, protein supplementation, antibiatic treatment of C. difficile, and surgical evaluation should be instituted as clinically indicated.

5.7 Persisting or Relapsing S. aureus Bacteremia/Endocarditis Patients with persisting or relapsing S. aureus bacteremia/Endocarditis or poor clinical response should have repeat blood cultures. If a blood culture is positive for S. aureus, minimum inhibitory concentration (MIC) susceptibility testing of the isolate should be performed using a standardized procedure, and diagnostic evaluation of the patient should be performed to rule out sequestered foci of infection. Appropriate surgical intervention (e.g., debridement, removal of prosthetic devices, valve replacement surgery) and/or consideration of a change in antibiatic regimen may be required.

Failure of treatment due to persisting or relapsing S. aureus bacteremia/endocarditis may be due to reduced daptomycin susceptibility (as evidenced by increasing MIC of the S. aureus isolate) [see Clinical Studies (14.2)].

5.8 Decreased Efficacy in Patients with Moderate Baseline Renal Impairment Limited data are available from the two Phase 3 complicated skin and skin structure infection (cSSSI) trials regarding clinical efficacy of daptomycin for injection treatment in patients with creatinine clearance (CLcr) <50 mL/min; only 31/534 (6%) patients treated with daptomycin for injection in the intent-to-treat (ITT) population had a baseline CLcr <50 mL/min. Table 2 shows the number of patients by renal function and treatment group who were clinical successes in the Phase 3 cSSSI trials.

Table 2. Clinical Success Rates by Renal Function and Treatment Group in Phase 3 cSSSI Trials (Population: ITT)

Table with 3 columns: CLcr, Daptomycin for Injection 4 mg/kg q24h, and Comparator. Shows success rates for different renal function groups.

In a subgroup analysis of the ITT population in the Phase 3 S. aureus bacteremia/endocarditis trial, clinical success rates, as determined by a treatment-blinded Adjudication Committee [see Clinical Studies (14.2)], in the Daptomycin for Injection-treated patients were lower in patients with baseline CLcr <50 mL/min (see Table 3). A decrease of the magnitude shown in Table 3 was not observed in comparator-treated patients.

Table 3. Adjudication Committee Clinical Success Rates at Test of Cure by Baseline Creatinine Clearance and Treatment Subgroup in the S. aureus Bacteremia/Endocarditis Trial (Population: ITT)

Table with 4 columns: Baseline CLcr, Daptomycin for Injection 6 mg/kg q24h, and Comparator. Shows success rates for different CLcr groups.

Consider these data when selecting antibiatic therapy for use in patients with baseline moderate to severe renal impairment.

5.9 Drug-Laboratory Test Interactions Clinically relevant plasma concentrations of daptomycin have been observed to cause a significant concentration-dependent false prolongation of prothrombin time (PT) and elevation of International Normalized Ratio (INR) when certain recombinant thromboplastin reagents are utilized for the assay [see Drug Interactions (7.2)].

5.10 Non-Susceptible Microorganisms The use of antibiatics may promote the overgrowth of non-susceptible microorganisms. If superinfection occurs during therapy, appropriate measures should be taken. Prescribing Daptomycin for Injection in the absence of a proven or strongly suspected bacterial infection is unlikely to provide benefit to the patient and increases the risk of the development of drug-resistant bacteria.

6 ADVERSE REACTIONS

The following adverse reactions are described, or described in greater detail, in other sections:

- Anaphylaxis/hypersensitivity reactions [see Warnings and Precautions (5.1)]
- Myopathy and rhabdomyolysis [see Warnings and Precautions (5.2)]
- Eosinophilic pneumonia [see Warnings and Precautions (5.3)]
- Peripheral neuropathy [see Warnings and Precautions (5.4)]
- Increased International Normalized Ratio (INR)/prolonged prothrombin time [see Warnings and Precautions (5.9) and Drug Interactions (7.2)]

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared with rates in the clinical trials of another drug and may not reflect the rates observed in practice.

6.1 Clinical Trials Experience

Clinical trials enrolled 1,864 patients treated with Daptomycin for Injection and 1,416 treated with comparator.

Complicated Skin and Skin Structure Infection Trials In Phase 3 complicated skin and skin structure infection (cSSSI) trials, Daptomycin for Injection was discontinued in 15/534 (2.8%) patients due to an adverse reaction, while comparator was discontinued in 17/558 (3.0%) patients.

The rates of the most common adverse reactions, organized by body system, observed in cSSSI (4 mg/kg Daptomycin for Injection) patients are displayed in Table 4.

Table 4. Incidence of Adverse Reactions that Occurred in ≥2% of Patients in the Daptomycin for Injection Treatment Group and ≥ the Comparator Treatment Group in Phase 3 cSSSI Trials

Table with 3 columns: Adverse Reaction, Daptomycin for Injection 4 mg/kg (N=534), and Comparator* (N=558). Lists various adverse reactions and their incidence.

* Comparator: vancomycin (1 g IV q12h) or an anti-staphylococcal semi-synthetic penicillin (i.e., nafcillin, oxacillin, cloxacillin, or flucloxacillin; 4 to 12 g/day IV in divided doses).

Drug-related adverse reactions (possibly or probably drug-related) that occurred in <1% of patients receiving Daptomycin for Injection in the cSSSI trials are as follows:

- Body as a Whole: fatigue, weakness, rigors, flushing, hypersensitivity
- Blood/Lymphatic System: leukocytosis, thrombocytopenia, thrombocytosis, eosinophilia, increased International Normalized Ratio (INR)
- Cardiovascular System: supraventricular arrhythmia
- Dermatologic System: eczema
- Digestive System: abdominal distension, stomatitis, jaundice, increased serum lactate dehydrogenase
- Metabolic/Nutritional System: hypogonadism, increased serum bicarbonate, electrolyte disturbance
- Musculoskeletal System: myalgia, muscle cramps, muscle weakness, arthralgia
- Nervous System: vertigo, mental status change, paresthesia
- Special Senses: taste disturbance, eye irritation
- S. aureus Bacteremia/Endocarditis Trial In the S. aureus bacteremia/endocarditis trial, Daptomycin for Injection was discontinued in 20/120 (16.7%) patients due to an adverse reaction, while comparator was discontinued in 21/116 (18.1%) patients. Serious Gram-negative infections (including bloodstream infections) were reported in 10/120 (8.3%) Daptomycin for Injection-treated and 0/115 comparator-treated patients. Comparator-treated patients received dual therapy that included initial gentamicin for 4 days. Infections were reported during treatment and during early and late follow-up. Gram-negative infections included cholangitis, alcoholic pancreatitis, sternal osteomyelitis/mediastinitis, bowel infarction, recurrent Crohn's disease, recurrent listeria sepsis, and recurrent urethritis caused by a number of different Gram-negative bacteria.

The rates of the most common adverse reactions, organized by System Organ Class (SOC), observed in S. aureus bacteremia/endocarditis (6 mg/kg Daptomycin for Injection) patients are displayed in Table 5.

Table 5. Incidence of Adverse Reactions that Occurred in ≥2% of Patients in the Daptomycin for Injection Treatment Group and ≥ the Comparator Treatment Group in the S. aureus Bacteremia/Endocarditis Trial

Table with 3 columns: Adverse Reaction*, Daptomycin for Injection 6 mg/kg (N=120), and Comparator† (N=116). Lists various adverse reactions and their incidence.

* NOS, not otherwise specified.

† Comparator: vancomycin (1 g IV q12h) or an anti-staphylococcal semi-synthetic penicillin (i.e., nafcillin, oxacillin, cloxacillin, or flucloxacillin; 2 g IV q4h), each with initial low-dose gentamicin.

The following reactions, not included above, were reported as possibly or probably drug-related in the Daptomycin for Injection-treated group:

- Blood and Lymphatic System Disorders: eosinophilia, lymphadenopathy, thrombocytopenia, thrombocytopenia
- Cardiac Disorders: atrial fibrillation, atrial flutter, cardiac arrest
- Ear and Labyrinthine Disorders: tinnitus
- Eye Disorders: vision blurred
- Gastrointestinal Disorders: dry mouth, epigastric discomfort, gingival pain, hyposthesia oral
- Infections and Infestations: candidal infection NOS, vaginal candidiasis, fungemia, oral candidiasis, urinary tract infection/fungus
- Investigations: blood phosphorus increased, blood alkaline phosphatase increased, INR increased, liver function test abnormal, alanine aminotransferase increased, aspartate aminotransferase increased, prothrombin time prolonged
- Metabolism and Nutrition Disorders: appetite decreased NOS
- Musculoskeletal and Connective Tissue Disorders: myalgia
- Nervous System Disorders: dyskinesia, paresthesia
- Psychiatric Disorders: hallucination NOS
- Renal and Urinary Disorders: proteinuria, renal impairment NOS
- Skin and Subcutaneous Tissue Disorders: pruritus generalized, rash vesicular

Other Trials

In Phase 3 trials of community-acquired pneumonia (CAP), the death rate and rates of serious cardiovascular adverse events were higher in Daptomycin for Injection-treated patients than in comparator-treated patients. These differences were due to lack of therapeutic effectiveness of Daptomycin for Injection in the treatment of CAP in patients experiencing these adverse events [see Indications and Usage (1.3)].

Laboratory Changes

Complicated Skin and Skin Structure Infection Trials In Phase 3 cSSSI trials of Daptomycin for Injection at a dose of 4 mg/kg, elevations in CPK were reported as clinical adverse events in 15/534 (2.8%) Daptomycin for Injection-treated patients, compared with 10/558 (1.8%) comparator-treated patients. Of the 534 patients treated with Daptomycin for Injection, 1 (0.2%) had symptoms of muscle pain or weakness associated with CPK elevations to greater than 4 times the upper limit of normal (ULN). The symptoms resolved within 3 days and CPK returned to normal within 7 to 10 days after treatment was discontinued [see Warnings and Precautions (5.2)]. Table 6 summarizes the CPK shifts from Baseline through End of Therapy in the cSSSI trials.

Table 6. Incidence of CPK Elevations from Baseline during Therapy in Either the Daptomycin for Injection Treatment Group or the Comparator Treatment Group in Phase 3 cSSSI Trials

Table with 4 columns: All Patients, Patients with Normal CPK at Baseline, Daptomycin for Injection 4 mg/kg (N=430), and Comparator* (N=459). Shows CPK elevation data.

Note: Elevations in CPK observed in patients treated with Daptomycin for Injection or comparator were not clinically or statistically significant.

* Comparator: vancomycin (1 g IV q12h) or an anti-staphylococcal semi-synthetic penicillin (i.e., nafcillin, oxacillin, cloxacillin, or flucloxacillin; 4 to 12 g/day IV in divided doses).

† ULN (Upper Limit of Normal) is defined as 200 U/L.

S. aureus Bacteremia/Endocarditis Trial

In the S. aureus bacteremia/endocarditis trial, at a dose of 6 mg/kg, 11/120 (9.2%) Daptomycin for Injection-treated patients, including two patients with baseline CPK levels >500 U/L, had CPK elevations to levels >500 U/L, compared with 1/116 (0.9%) comparator-treated patients. Of the 11 Daptomycin for Injection-treated patients, 4 had prior or concomitant treatment with an HMG-CoA reductase inhibitor. Three of these 11 Daptomycin for Injection-treated patients discontinued therapy due to CPK elevation, while the one comparator-treated patient did not discontinue therapy [see Warnings and Precautions (5.2)].

6.2 Post-Marketing Experience

The following adverse reactions have been identified during post-approval use of Daptomycin for Injection. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to estimate their frequency reliably or establish a causal relationship to drug exposure.

Blood and lymphatic system disorders: anemia

General and administration site conditions: pyrexia

Immune System Disorders: anaphylaxis; hypersensitivity reactions, including angioedema, drug rash with eosinophilia and systemic symptoms (DRESS), pruritus, hives, shortness of breath, difficulty swallowing, truncal erythema, and pulmonary eosinophilia [see Contraindications (4), Warnings and Precautions (5.1)]

Infections and Infestations: Clostridium difficile-associated diarrhea [see Warnings and Precautions (5.6)]

Musculoskeletal Disorders: myoglobin increased; rhabdomyolysis (some reports involved patients treated concomitantly with Daptomycin for Injection and HMG-CoA reductase inhibitors) [see Warnings and Precautions (5.2), Drug Interactions (7.2), and Clinical Pharmacology (12.3)]

Respiratory, Thoracic, and Mediastinal Disorders: cough, eosinophilic pneumonia [see Warnings and Precautions (5.3)]

Nervous System Disorders: peripheral neuropathy [see Warnings and Precautions (5.4)]

Skin and Subcutaneous Tissue Disorders: serious skin reactions, including Stevens-Johnson syndrome and vesiculobullous rash (with or without mucous membrane involvement); acute generalized exanthematous pustulosis

Gastrointestinal Disorders: nausea, vomiting

Renal and urinary disorders: acute kidney injury, renal insufficiency, and renal failure

Special Senses: visual disturbances

7 DRUG INTERACTIONS

7.1 HMG-CoA Reductase Inhibitors

In healthy subjects, concomitant administration of Daptomycin for Injection and simvastatin had no effect on plasma trough concentrations of simvastatin, and there were no reports of skeletal myopathy [see Clinical Pharmacology (12.3)].

However, inhibitors of HMG-CoA reductase may cause myopathy, which is manifested as muscle pain or weakness associated with elevated levels of creatine phosphokinase (CPK). In the Phase 3 S. aureus bacteremia/endocarditis trial, some patients who received prior or concomitant treatment with a recombinant thromboplastin reagent may be minimized by drawing specimens for PT or INR testing near the time of trough plasma concentrations of daptomycin. However, sufficient daptomycin concentrations may be present at trough to cause interaction.

If confronted with an abnormally high PT/INR result in a patient being treated with Daptomycin for Injection, it is recommended that clinicians:

- 1. Repeat the assessment of PT/INR, requesting that the specimen be drawn just prior to the next Daptomycin for Injection dose (i.e., at trough concentration). If the PT/INR value obtained at trough remains substantially elevated above what would otherwise be expected, consider evaluating PT/INR utilizing an alternative method.
2. Evaluate for other causes of abnormally elevated PT/INR results.

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Teratogenic Effects: Pregnancy Category B There are no adequate and well-controlled trials of Daptomycin for Injection in pregnant women.

Embryofetal development studies performed in rats and rabbits at doses of up to 75 mg/kg (2 and 4 times the 6 mg/kg human dose, respectively), on a body surface area basis) revealed no evidence of harm to the fetus due to daptomycin. Because animal reproduction studies are not always predictive of human response, Daptomycin for Injection should be used during pregnancy only if the potential benefit outweighs the possible risk.

8.2 Nursing Mothers

Daptomycin is present in human milk but is poorly bioavailable orally. In a single case study, daptomycin was administered daily for 28 days to a nursing mother at an IV dose of 6.7 mg/kg/day, and samples of the patient's breast milk were collected over a 24-hour period on day 27. The highest measured concentration of daptomycin in the breast milk was 0.045 mcg/mL. The calculated maximum daily daptomycin dose to the infant (assuming mean milk consumption of 150 mL/kg/day) was 0.1% of the maternal dose (6.7 mg/kg/day) [see Nonclinical Toxicology (13.2)]. Caution should be exercised when daptomycin is administered to a nursing woman.

8.4 Pediatric Use

Safety and effectiveness of Daptomycin for Injection in pediatric patients have not been established. Avoid use of Daptomycin for Injection in pediatric patients younger than 12 months due to the risk of potential effects on muscular, neuromuscular, and/or nervous systems (either peripheral and/or central) observed in neonatal dogs [see Warnings and Precautions (5.5) and Nonclinical Toxicology (13.2)].

8.5 Geriatric Use

Of the 534 patients treated with Daptomycin for Injection in Phase 3 controlled clinical trials of complicated skin and skin structure infections (cSSSI), 27% were 65 years of age or older and 12% were 75 years of age or older. Of the 120 patients treated with Daptomycin for Injection in the Phase 3 controlled clinical trial of S. aureus bacteremia/endocarditis, 25% were 65 years of age or older and 16% were 75 years of age or older. In Phase 3 clinical trials of cSSSI and S. aureus bacteremia/endocarditis, clinical success rates were lower in patients ≥65 years of age than in patients <65 years of age. In addition, treatment-emergent adverse events were more common in patients ≥65 years of age than in patients <65 years of age.

The exposure of daptomycin was higher in healthy elderly subjects than in healthy young subjects. However, no adjustment of Daptomycin for Injection dosage is warranted for elderly patients with creatinine clearance (CLcr) ≥30 mL/min [see Dosage and Administration (2.4) and Clinical Pharmacology (12.3)].

8.6 Patients with Renal Impairment

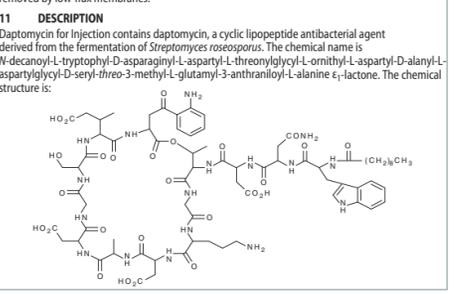

Daptomycin is eliminated primarily by the kidneys; therefore, a modification of Daptomycin for Injection dosage interval is recommended for patients with CLcr <30 mL/min, including patients receiving hemodialysis or continuous ambulatory peritoneal dialysis (CAPD). In patients with renal impairment, both renal function and creatine phosphokinase (CPK) should be monitored more frequently than once weekly [see Dosage and Administration (2.4), Warnings and Precautions (5.2, 5.8), and Clinical Pharmacology (12.3)].

10 OVERDOSAGE

In the event of overdose, supportive care is advised with maintenance of glomerular filtration. Daptomycin is cleared slowly from the body by hemodialysis (approximately 15% of the administered dose is removed over 4 hours) and by peritoneal dialysis (approximately 11% of the administered dose is removed over 48 hours). The use of high-flux dialysis membranes during 4 hours of hemodialysis may increase the percentage of dose removed compared with that removed by low-flux membranes.

11 DESCRIPTION

Daptomycin for Injection contains daptomycin, a cyclic lipopeptide antibiatic agent derived from the fermentation of Streptomyces species. The chemical name is: N-decanoyl-L-tryptophyl-D-asparaginyl-L-aspartyl-L-threonylglycyl-L-ornithyl-L-aspartyl-D-alanyl-L-aspartylglycyl-D-seryl-threo-3-methyl-L-glutamyl-3-anthraniloyl-L-alanine ε1-lactone. The chemical structure is:

The empirical formula is C₂₇H₄₁N₇O₁₃; the molecular weight is 1620.67. Daptomycin for Injection is supplied in a single-dose vial as a sterile, preservative-free, pale yellow to light brown, lyophilized cake or powder containing approximately 500 mg of daptomycin for intravenous (IV) use following reconstitution with 0.9% sodium chloride injection [see Dosage and Administration (2.5)]. The only inactive ingredient is sodium hydroxide, which is used for pH adjustment. Freshly reconstituted solutions of Daptomycin for Injection range in color from pale yellow to light brown.

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

Daptomycin is an antibacterial drug [see Clinical Pharmacology (12.1)].

12.2 Pharmacodynamics

Based on animal models of infection, the antimicrobial activity of daptomycin appears to correlate with the AUC/MIC (area under the concentration-time curve/minimum inhibitory concentration) ratio for certain pathogens, including *S. aureus*. The principal pharmacokinetic/pharmacodynamic parameter best associated with clinical and microbiological cure has not been elucidated in clinical trials with Daptomycin for Injection.

12.3 Pharmacokinetics

Daptomycin for Injection Administered over a 30-Minute Period The mean and standard deviation (SD) pharmacokinetic parameters of daptomycin at steady-state following intravenous (IV) administration of Daptomycin for Injection over a 30-minute period at 4 to 12 mg/kg q24h to healthy young adults are summarized in Table 7.

Table 7. Mean (SD) Daptomycin Pharmacokinetic Parameters in Healthy Volunteers at Steady-State

Table with 6 columns: Dose† (mg/kg), AUC₀₋₂₄ (mcg·h/mL), t_{1/2} (h), V_d (L/kg), CL† (mL/h/kg), and C_{max} (mcg/mL). Rows show data for doses of 4, 6, 8, 10, and 12 mg/kg.

Daptomycin for Injection was administered by IV infusion over a 30-minute period. † Doses of Daptomycin for Injection in excess of 6 mg/kg have not been approved. ‡ AUC₀₋₂₄, area under the concentration-time curve from 0 to 24 hours; t_{1/2}, elimination half-life; V_d, volume of distribution at steady-state; CL†, total plasma clearance; C_{max}, maximum plasma concentration.

Daptomycin pharmacokinetics were generally linear and time-independent at Daptomycin for Injection doses of 4 to 12 mg/kg q24h administered by IV infusion over a 30-minute period for up to 14 days. Steady-state trough concentrations were achieved by the third daily dose. The mean (SD) steady-state trough concentrations attained following the administration of 4, 6, 8, 10, and 12 mg/kg q24h were 5.9 (1.6), 6.7 (1.6), 10.3 (5.5), 12.9 (2.9), and 13.7 (5.2) mcg/mL, respectively.

Daptomycin for Injection Administered over a 2-Minute Period Following IV administration of Daptomycin for Injection over a 2-minute period to healthy volunteers at doses of 4 mg/kg (N=8) and 6 mg/kg (N=12), the mean (SD) steady-state systemic exposure (AUC) values were 475 (71) and 701 (82) mcg·h/mL, respectively. Values for maximum plasma concentration (C_{max}) at the end of the 2-minute period could not be determined adequately in this study. However, using pharmacokinetic parameters from 14 healthy volunteers who received a single dose of Daptomycin for Injection 6 mg/kg IV administered over a 30-minute period in a separate study, steady-state C_{max} values were simulated for Daptomycin for Injection 4 and 6 mg/kg IV administered over a 2-minute period. The simulated mean (SD) steady-state C_{max} values were 77.7 (8.1) and 116.6 (12.2) mcg/mL, respectively.

Distribution Daptomycin is reversibly bound to human plasma proteins, primarily to serum albumin, in a concentration-independent manner. The overall mean binding ranges from 90 to 93%. In clinical studies, mean serum protein binding in subjects with creatinine clearance (CL_{CR}) ≥30 mL/min was comparable to that observed in healthy subjects with normal renal function. However, there was a trend toward decreasing serum protein binding among subjects with CL_{CR} <30 mL/min (88%), including those receiving hemodialysis (86%) and continuous ambulatory peritoneal dialysis (CAPD) (84%). The protein binding of daptomycin in subjects with moderate hepatic impairment (Child-Pugh Class B) was similar to that in healthy adult subjects. The volume of distribution at steady-state (V_d) of daptomycin in healthy adult subjects was approximately 0.1 L/kg and was independent of dose.

Metabolism In *in vitro* studies, daptomycin was not metabolized by human liver microsomes. In 5 healthy adults after infusion of radiolabeled ¹⁴C-daptomycin, the plasma total radioactivity was similar to the concentration determined by microbiological assay. Inactive metabolites were detected in urine, as determined by the difference between total radioactive concentrations and microbiologically active concentrations. In a separate study, no metabolites were observed in plasma on Day 1 following the administration of Daptomycin for Injection at 6 mg/kg to subjects. Minor amounts of three oxidative metabolites and one unidentified compound were detected in urine. The site of metabolism has not been identified.

Excretion Daptomycin is excreted primarily by the kidneys. In a mass balance study of 5 healthy subjects using radiolabeled daptomycin, approximately 78% of the administered dose was recovered from urine based on total radioactivity (approximately 52% of the dose based on microbiologically active concentrations), and 5.7% of the administered dose was recovered from feces (collected for up to 9 days) based on total radioactivity.

Specific Populations

Renal Impairment

Population-derived pharmacokinetic parameters were determined for infected patients (complicated skin and skin structure infections [cSSSI] and *S. aureus* bacteremia) and noninfected subjects with various degrees of renal function (Table 8). Total plasma clearance (CL_T), elimination half-life (t_{1/2}), and volume of distribution at steady-state (V_d) in patients with cSSSI were similar to those in patients with *S. aureus* bacteremia. Following administration of Daptomycin for Injection 4 mg/kg q24h by IV infusion over a 30-minute period, the mean CL_T was 7% higher, and 46% lower among subjects and patients with mild (CL_{CR} 30–50 mL/min), moderate (CL_{CR} 15–30 mL/min), and severe (CL_{CR} <15 mL/min) renal impairment, respectively, than in those with normal renal function (CL_{CR} ≥80 mL/min). The mean steady-state systemic exposure (AUC₀₋₂₄) and V_d increased with decreasing renal function, although the mean AUC for patients with CL_{CR} 30–80 mL/min was not markedly different from the mean AUC for patients with normal renal function. The mean AUC for patients with CL_{CR} <30 mL/min and for patients on dialysis (CAPD and hemodialysis) dosed post-dialysis was approximately 2- and 3-times higher, respectively, than for patients with normal renal function. The mean C_{max} ranged from 60 to 70 mcg/mL in patients with CL_{CR} ≥30 mL/min, while the mean C_{max} for patients with CL_{CR} <30 mL/min ranged from 41 to 58 mcg/mL. After administration of Daptomycin for Injection 6 mg/kg q24h by IV infusion over a 30-minute period, the mean C_{max} ranged from 80 to 114 mcg/mL in patients with mild to moderate renal impairment and was similar to that of patients with normal renal function.

Hepatic Impairment The pharmacokinetics of daptomycin were evaluated in 10 subjects with moderate hepatic impairment (Child-Pugh Class B) and compared with those in healthy volunteers (N=9) matched for gender, age, and weight. The pharmacokinetics of daptomycin were not altered in subjects with moderate hepatic impairment. No dosage adjustment is warranted when Daptomycin for Injection is administered to patients with mild to moderate hepatic impairment. The pharmacokinetics of daptomycin in patients with severe hepatic impairment (Child-Pugh Class C) have not been evaluated.

Gender No clinically significant gender-related differences in daptomycin pharmacokinetics have been observed. No dosage adjustment is warranted based on gender when Daptomycin for Injection is administered.

Geriatric The pharmacokinetics of daptomycin were evaluated in 12 healthy elderly subjects (≥75 years of age) and 11 healthy young controls (18 to 30 years of age). Following administration of a single 4 mg/kg dose of Daptomycin for Injection by IV infusion over a 30-minute period, the mean total clearance of daptomycin was approximately 35% lower and the mean AUC₀₋₂₄ was approximately 58% higher in elderly subjects than in healthy young subjects. There were no differences in C_{max} [see *Use in Specific Populations* (8.5)].

Obesity The pharmacokinetics of daptomycin were evaluated in 6 moderately obese (Body Mass Index [BMI] 25 to 39.9 kg/m²) and 6 extremely obese (BMI ≥40 kg/m²) subjects and controls matched for age, gender, and renal function. Following administration of Daptomycin for Injection by IV infusion over a 30-minute period as a single 4 mg/kg dose based on total body weight, the total plasma clearance of daptomycin normalized to total body weight was approximately 15% lower in moderately obese subjects and 23% lower in extremely obese subjects than in nonobese controls. The AUC₀₋₂₄ of daptomycin was approximately 30% higher in moderately obese subjects and 31% higher in extremely obese subjects than in nonobese controls. The differences were most likely due to differences in the renal clearance of daptomycin. No adjustment of Daptomycin for Injection dosage is warranted in obese patients.

Pediatric The pharmacokinetics of daptomycin in pediatric populations (<18 years of age) have not been established [see *Nonclinical Toxicology* (13.2)].

Drug-Drug Interactions

In Vitro Studies

In *in vitro* studies with human hepatocytes indicate that daptomycin does not inhibit or induce the activities of the following human cytochrome P450 isoforms: 1A2, 2A6, 2C9, 2C19, 2D6, 2E1, and 3A4. It is unlikely that daptomycin will inhibit or induce the metabolism of drugs metabolized by the P450 system.

Aztreonam In a study in which 15 healthy adult subjects received a single dose of Daptomycin for Injection 6 mg/kg IV and a combination dose of Daptomycin for Injection 6 mg/kg IV and aztreonam 1 g IV, administered over a 30-minute period, the C_{max} and AUC₀₋₂₄ of daptomycin were not significantly altered by aztreonam.

Tobramycin In a study in which 6 healthy adult males received a single dose of Daptomycin for Injection 2 mg/kg IV, tobramycin 1 mg/kg IV, and both in combination, administered over a 30-minute period, the mean C_{max} and AUC₀₋₂₄ of daptomycin were 12.7% and 8.7% higher, respectively, when Daptomycin for Injection was coadministered with tobramycin. The mean C_{max} and AUC₀₋₂₄ of tobramycin were 10.7% and 6.6% lower, respectively, when tobramycin was coadministered with Daptomycin for Injection. These differences were not statistically significant. The interaction between daptomycin and tobramycin with a clinical dose of Daptomycin for Injection is unknown.

Warfarin In 16 healthy subjects, administration of Daptomycin for Injection 6 mg/kg q24h by IV infusion over a 30-minute period for 5 days, with coadministration of a single oral dose of warfarin (25 mg) on the 5th day, had no significant effect on the pharmacokinetics of either drug and did not significantly alter the INR (International Normalized Ratio).

Simvastatin In 20 healthy subjects on a stable daily dose of simvastatin 40 mg, administration of Daptomycin for Injection 4 mg/kg q24h by IV infusion over a 30-minute period for 14 days (N=10) had no effect on plasma trough concentrations of simvastatin and was not associated with a higher incidence of adverse events, including skeletal myopathy, than in subjects receiving placebo once daily (N=10) [see *Warnings and Precautions* (5.2) and *Drug Interactions* (7.1)].

Probenecid Concomitant administration of probenecid (500 mg 4 times daily) and a single dose of Daptomycin for Injection 4 mg/kg by IV infusion over a 30-minute period did not significantly alter the C_{max} or AUC₀₋₂₄ of daptomycin.

Microbiology Daptomycin belongs to the cyclic lipopeptide class of antibacterials. Daptomycin has clinical utility in the treatment of infections caused by aerobic, Gram-positive bacteria. The *in vitro* spectrum of activity of daptomycin encompasses most clinically relevant Gram-positive pathogenic bacteria. Daptomycin exhibits rapid, concentration-dependent bactericidal activity against Gram-positive bacteria *in vitro*. This has been demonstrated both by time-kill curves and by MBC/MIC (minimum bactericidal concentration/minimum inhibitory concentration) ratios using broth dilution methodology. Daptomycin maintained bactericidal activity *in vitro* against stationary phase *S. aureus* in simulated endocardial vegetations. The clinical significance of this is not known.

Mechanism of Action The mechanism of action of daptomycin is distinct from that of any other antibacterial. Daptomycin binds to bacterial cell membranes and causes a rapid depolarization of membrane potential. This loss of membrane potential causes inhibition of DNA, RNA, and protein synthesis, which results in bacterial cell death.

Mechanism of Resistance The mechanism(s) of daptomycin resistance is not fully understood. Currently, there are no known transferable elements that confer resistance to daptomycin. Complicated Skin and Skin Structure Infection (cSSSI) Trials The emergence of daptomycin non-susceptible isolates occurred in 2 infected patients across the set of Phase 2 and pivotal Phase 3 clinical trials of cSSSI. In one case, a non-susceptible *S. aureus* was isolated from a patient in a Phase 2 trial who received Daptomycin for Injection at less than the protocol-specified dose for the initial 5 days of therapy. In the second case, a non-susceptible *Enterococcus faecalis* was isolated from a patient with an infected chronic decubitus ulcer who was enrolled in a salvage trial.

S. aureus Bacteremia/Endocarditis and Other Post-Approval Trials In subsequent clinical trials, non-susceptible isolates were recovered. *S. aureus* was isolated from a patient in a compassionate-use trial and from 7 patients in the *S. aureus* bacteremia/endocarditis trial [see *Clinical Studies* (14.2)]. An *E. faecium* was isolated from a patient in a vancomycin-resistant enterococci trial.

Interactions with Other Antibacterials *In vitro* studies have investigated daptomycin interactions with other antibacterials. Antagonism, as determined by kill curve studies, has not been observed. *In vitro* synergistic interactions of daptomycin with aminoglycosides, β-lactam antibacterials, and rifampin have been shown against some isolates of *Staphylococcus* (including some methicillin-resistant isolates) and enterococci (including some vancomycin-resistant isolates).

Activity *In Vitro and In Vivo* Daptomycin has been shown to be active against most isolates of the following Gram-positive bacteria both *in vitro* and in clinical infections, as described in *Indications and Usage* (1).

Gram-Positive Bacteria *Enterococcus faecalis* (vancomycin-susceptible isolates only) *Streptococcus aureus* (including methicillin-resistant isolates) *Staphylococcus agalactiae* *Streptococcus dysgalactiae* subsp. *equisimilis* *Streptococcus pyogenes*

The following *in vitro* data are available, but their clinical significance is unknown. At least 90% of the following Gram-positive bacteria exhibit an *in vitro* minimum inhibitory concentration (MIC) less than or equal to the susceptible breakpoint for daptomycin versus the bacterial genus (Table 9). However, the efficacy of Daptomycin for Injection in treating clinical infections due to these bacteria has not been established in adequate and well-controlled clinical trials.

Gram-Positive Bacteria *Corynebacterium jeikeium* *Enterococcus faecalis* (vancomycin-resistant isolates) *Enterococcus faecium* (including vancomycin-resistant isolates) *Staphylococcus epidermidis* (including methicillin-resistant isolates) *Staphylococcus haemolyticus* *Staphylococcus hominis*

When available, the clinical microbiology laboratory should provide the results of *in vitro* susceptibility tests for antimicrobial drug products used in resident hospitals to the physician as periodic reports that describe the susceptibility profile of nosocomial and community-acquired pathogens. These reports should aid the physician in selecting an antibacterial drug product for treatment.

Dilution Techniques Quantitative methods are used to determine antimicrobial minimum inhibitory concentrations (MICs). These MICs provide estimates of the susceptibility of bacteria to antimicrobial compounds. The MICs should be determined using a standardized broth method[†] with the broth adjusted to a calcium content of 50 mg/L. The use of the agar dilution method is not recommended with daptomycin[†]. The MICs should be interpreted according to the criteria listed in Table 9.

Note: S, Susceptible; I, Intermediate; R, Resistant. † The MIC interpretive criteria for *S. aureus* and *E. faecalis* are applicable only to tests performed by broth dilution using Mueller-Hinton broth adjusted to a calcium content of 50 mg/L; the MIC interpretive criteria for *Streptococcus spp.* other than *S. pneumoniae* are applicable only to tests performed by broth dilution using Mueller-Hinton broth adjusted to a calcium content of 50 mg/L, supplemented with 2 to 5% lysed horse blood, inoculated with a direct colony suspension and incubated in ambient air at 35°C for 20 to 24 hours.

† The current absence of data on daptomycin-resistant isolates precludes defining any categories other than "Susceptible." Isolates yielding test results suggestive of a "Non-Susceptible" category should be retested, and if the result is confirmed, the isolate should be submitted to a reference laboratory for further testing.

A report of "Susceptible" indicates that the antimicrobial is likely to inhibit the growth of the pathogen if the antimicrobial compound reaches the concentration at the infection site necessary to inhibit growth of the pathogen.

Dilution Technique Quantitative methods that require measurement of zone diameters have not been shown to provide reproducible estimates of the susceptibility of bacteria to daptomycin. The use of the disk diffusion method is not recommended with daptomycin[†].

Quality Control Standardized susceptibility test procedures require the use of laboratory controls to monitor and ensure the accuracy and precision of supplies and reagents used in the assay, and the techniques of the individuals performing the tests[‡]. Standard daptomycin powder should provide the ranges of MIC values noted in Table 10.

Table 10. Acceptable Quality Control Ranges for Daptomycin to Be Used in Validation of Susceptibility Test Results

Table with 2 columns: Quality Control Strain and Broth Dilution MIC Range* (mcg/mL). Rows include Enterococcus faecalis ATCC 29212, Staphylococcus aureus ATCC 29213, and Streptococcus pneumoniae ATCC 49619†.

* The quality control ranges for *S. aureus* and *E. faecalis* are applicable only to tests performed by broth dilution using Mueller-Hinton broth adjusted to a calcium content of 50 mg/L; the quality control range for *Streptococcus pneumoniae* is applicable only to tests performed by broth dilution using Mueller-Hinton broth adjusted to a calcium content of 50 mg/L, supplemented with 2 to 5% lysed horse blood, inoculated with a direct colony suspension and incubated in ambient air at 35°C for 20 to 24 hours.

† This strain may be used for validation of susceptibility test results when testing *Streptococcus spp.* other than *S. pneumoniae*.

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

Long-term carcinogenicity studies in animals have not been conducted to evaluate the carcinogenic potential of Daptomycin for Injection. However, neither mutagenic nor clastogenic potential was found in a battery of genotoxicity tests, including the Ames assay, a mammalian cell gene mutation assay, a test for chromosomal aberrations in Chinese hamster ovary cells, an *in vivo* micronucleus assay, an *in vitro* DNA repair assay, and an *in vivo* sister chromatid exchange assay in Chinese hamsters.

Daptomycin did not affect the fertility or reproductive performance of male and female rats when administered intravenously at doses up to 150 mg/kg/day, which is approximately 9 times the estimated human exposure level based upon AUCs.

13.2 Animal Toxicology and/or Pharmacology

Adult Animals

In animals, daptomycin administration has been associated with effects on skeletal muscle. However, there were no changes in cardiac or smooth muscle. Skeletal muscle effects were characterized by microscopic degenerative/regenerative changes and variable elevations in creatine phosphokinase (CPK). No fibrosis or rhabdomyolysis was evident in repeat-dose studies up to the highest doses tested in rats (150 mg/kg/day) and dogs (100 mg/kg/day). The degree of skeletal myopathy showed no increase when treatment was extended from 1 month to up to 6 months. Severity was dose-dependent. All muscle effects, including microscopic changes, were fully reversible within 30 days following the cessation of dosing.

In adult animals, effects on peripheral nerve (characterized by axonal degeneration and frequently accompanied by significant loss of plexus, reflex, gag reflex, and pain perception) were observed at daptomycin doses higher than those associated with skeletal myopathy. Deficits in the dogs' patellar reflexes were seen within 2 weeks after the start of treatment at 40 mg/kg/day (9 times the human C_{max} at the 6 mg/kg/day dose), with some clinical improvement noted within 2 weeks after the cessation of dosing. However, at 75 mg/kg/day for 1 month, 7 of 8 dogs failed to regain full patellar reflex responses within a 3-month recovery period. In a separate study in dogs receiving doses of 75 and 100 mg/kg/day for 2 weeks, minimal residual histological changes were noted at 6 months after the cessation of dosing. However, recovery of peripheral nerve function was evident. Tissue distribution studies in rats showed that daptomycin is retained in the kidney but appears to penetrate the blood-brain barrier only minimally following single and multiple doses.

Juvenile Animals

Target organs of daptomycin-related effects in 7-week-old juvenile dogs were skeletal muscle and nerve, the same target organs as in adult dogs. In juvenile dogs, nerve effects were noted at lower daptomycin blood concentrations than in adult dogs following 28 days of dosing. In contrast to adult dogs, juvenile dogs also showed evidence of effects in nerves of the spinal cord as well as peripheral nerves after 28 days of dosing. No nerve effects were noted in juvenile dogs following 14 days of dosing at doses up to 75 mg/kg/day.

Administration of daptomycin to 7-week-old juvenile dogs for 28 days at doses of 50 mg/kg/day produced minimal degenerative effects on the peripheral nerve and spinal cord in several animals, with no corresponding clinical signs. A dose of 150 mg/kg/day for 28 days produced minimal degeneration in the peripheral nerve and spinal cord as well as minimal to mild degeneration of the skeletal muscle in a majority of animals, accompanied by slight to severe muscle weakness evident in most dogs. Following a 28-day recovery phase, microscopic examination revealed recovery of the skeletal muscle and the ulnar nerve effects, but nerve degeneration in the sciatic nerve and spinal cord was still observed in all 150 mg/kg/day dogs.

Following once-daily administration of daptomycin to juvenile dogs for 28 days, microscopic effects in nerve tissue were noted at a C_{max} value of 417 mcg/mL, which is approximately 3-fold less than the C_{max} value associated with nerve effects in adult dogs treated once daily with daptomycin for 28 days (1308 mcg/mL).

Neonatal Animals

Neonatal dogs (4 to 31 days old) were more sensitive to daptomycin-related adverse nervous system and/or muscular system effects than either juvenile or adult dogs. In neonatal dogs, adverse nervous system and/or muscular system effects were associated with a C_{max} value approximately 3-fold less than the C_{max} in juvenile dogs, and 9-fold less than the C_{max} in adult dogs following 28 days of dosing. At a dose of 25 mg/kg/day with associated C_{max} and AUC₀₋₂₄ values of 147 mcg/mL and 717 mcg·h/mL, respectively (1.6 and 1.0-fold the adult human C_{max} and AUC, respectively, at the 6 mg/kg/day dose), mild clinical signs of twitching and one incidence of muscle rigidity were observed with no corresponding effect on body weight. These effects were found to be reversible within 28 days after treatment had stopped.

At higher dose levels of 50 and 75 mg/kg/day with associated C_{max} and AUC₀₋₂₄ values of ≥231 mcg/mL and ≥1470 mcg·h/mL, respectively, marked clinical signs of twitching, muscle rigidity in the limbs, and impaired use of limbs were observed. Resulting decreases in body weights and overall body condition at doses ≥50 mg/kg/day necessitated early discontinuation by PND19. Histopathological assessment did not reveal any daptomycin-related changes in the peripheral and central nervous system tissue, as well as in the skeletal muscle or other tissues assessed, at any dose level.

No adverse effects were observed in the dogs that received daptomycin at 10 mg/kg/day, the NOAEL, with associated C_{max} and AUC₀₋₂₄ values of 62 mcg/mL and 247 mcg·h/mL, respectively (or 0.6 and 0.4-fold the adult human C_{max} and AUC, respectively, at the 6 mg/kg/day dose).

14 CLINICAL STUDIES

14.1 Complicated Skin and Skin Structure Infections

Adult patients with clinically documented complicated skin and skin structure infections (cSSSI) (Table 11) were enrolled in two randomized, multinational, multicenter, investigator-blinded trials comparing Daptomycin for Injection (4 mg/kg IV q24h) with either vancomycin (1 g IV q12h) or an anti-staphylococcal penicillin (2 g IV q4h), oxacillin, cloxacillin, or flucloxacillin; 4 to 12 g IV per day. Patients could switch to oral therapy after a minimum of 4 days of IV treatment if clinical improvement was demonstrated. Patients known to have bacteremia at baseline were excluded. Patients with creatinine clearance (CL_{CR}) below 30 and 70 mL/min were to receive a lower dose of Daptomycin for Injection as specified in the protocol; however, the majority of patients in this subpopulation did not have the dose of Daptomycin for Injection adjusted.

At higher dose levels of 50 and 75 mg/kg/day with associated C_{max} and AUC₀₋₂₄ values of ≥231 mcg/mL and ≥1470 mcg·h/mL, respectively, marked clinical signs of twitching, muscle rigidity in the limbs, and impaired use of limbs were observed. Resulting decreases in body weights and overall body condition at doses ≥50 mg/kg/day necessitated early discontinuation by PND19. Histopathological assessment did not reveal any daptomycin-related changes in the peripheral and central nervous system tissue, as well as in the skeletal muscle or other tissues assessed, at any dose level.

No adverse effects were observed in the dogs that received daptomycin at 10 mg/kg/day, the NOAEL, with associated C_{max} and AUC₀₋₂₄ values of 62 mcg/mL and 247 mcg·h/mL, respectively (or 0.6 and 0.4-fold the adult human C_{max} and AUC, respectively, at the 6 mg/kg/day dose).

14.2 Complicated Skin and Skin Structure Infections

Adult patients with clinically documented complicated skin and skin structure infections (cSSSI) (Table 11) were enrolled in two randomized, multinational, multicenter, investigator-blinded trials comparing Daptomycin for Injection (4 mg/kg IV q24h) with either vancomycin (1 g IV q12h) or an anti-staphylococcal penicillin (2 g IV q4h), oxacillin, cloxacillin, or flucloxacillin; 4 to 12 g IV per day. Patients could switch to oral therapy after a minimum of 4 days of IV treatment if clinical improvement was demonstrated. Patients known to have bacteremia at baseline were excluded. Patients with creatinine clearance (CL_{CR}) below 30 and 70 mL/min were to receive a lower dose of Daptomycin for Injection as specified in the protocol; however, the majority of patients in this subpopulation did not have the dose of Daptomycin for Injection adjusted.

At higher dose levels of 50 and 75 mg/kg/day with associated C_{max} and AUC₀₋₂₄ values of ≥231 mcg/mL and ≥1470 mcg·h/mL, respectively, marked clinical signs of twitching, muscle rigidity in the limbs, and impaired use of limbs were observed. Resulting decreases in body weights and overall body condition at doses ≥50 mg/kg/day necessitated early discontinuation by PND19. Histopathological assessment did not reveal any daptomycin-related changes in the peripheral and central nervous system tissue, as well as in the skeletal muscle or other tissues assessed, at any dose level.

No adverse effects were observed in the dogs that received daptomycin at 10 mg/kg/day, the NOAEL, with associated C_{max} and AUC₀₋₂₄ values of 62 mcg/mL and 247 mcg·h/mL, respectively (or 0.6 and 0.4-fold the adult human C_{max} and AUC, respectively, at the 6 mg/kg/day dose).

Table 11. Investigator's Primary Diagnosis in the cSSSI Trials (Population: Intent-to-Treat)

Table with 4 columns: Primary Diagnosis, Study 9801 (N=264 / N=266), Study 9901 (N=270 / N=292), and Pooled (N=534 / N=558). Rows include Wound Infection, Major Abscess, Ulcer Infection, and Other Infection†.

* Comparator: vancomycin (1 g IV q12h) or an anti-staphylococcal semi-synthetic penicillin (i.e., nafcillin, oxacillin, cloxacillin, or flucloxacillin; 4 to 12 g/day IV in divided doses). † The majority of cases were subsequently categorized as complicated cellulitis, major abscesses, or traumatic wound infections.

One trial was conducted primarily in the United States and South Africa (study 9801), and the second was conducted at non-US sites only (study 9901). The two trials were similar in design but differed in patient characteristics, including history of diabetes and peripheral vascular disease. There were a total of 534 patients treated with Daptomycin for Injection and 558 treated with comparator in the two trials. The majority (89.7%) of patients received IV medication exclusively. The efficacy endpoints in both trials were the clinical success rates in the intent-to-treat (ITT) population and in the clinically evaluable (CE) population. In study 9801, clinical success rates in the ITT population were 62.5% (165/264) in patients treated with Daptomycin for Injection and 60.9% (162/266) in patients treated with comparator drugs. Clinical success rates in the CE population were 76.0% (158/208) in patients treated with Daptomycin for Injection and 76.7% (156/206) in patients treated with comparator drugs. In study 9901, clinical success rates in the ITT population were 80.4% (217/270) in patients treated with Daptomycin for Injection and 80.5% (235/292) in patients treated with comparator drugs. Clinical success rates in the CE population were 89.9% (214/238) in patients treated with Daptomycin for Injection and 90.4% (226/250) in patients treated with comparator drugs.

The success rates by pathogen for microbiologically evaluable patients are presented in Table 12.

Table 12. Clinical Success Rates by Infecting Pathogen in the cSSSI Trials (Population: Microbiologically Evaluable)

Table with 3 columns: Pathogen, Daptomycin for Injection, and Comparator*. Rows include Methicillin-susceptible Staphylococcus aureus (MSSA)†, Methicillin-resistant Staphylococcus aureus (MRSA)†, Streptococcus pyogenes, Streptococcus agalactiae, Streptococcus dysgalactiae subsp. Equisimilis, and Enterococcus faecalis (vancomycin-susceptible only).

* Comparator: vancomycin (1 g IV q12h) or an anti-staphylococcal semi-synthetic penicillin (i.e., nafcillin, oxacillin, cloxacillin, or flucloxacillin; 4 to 12 g/day IV in divided doses). † As determined by the central laboratory.

14.2 S. aureus Bacteremia/Endocarditis

The efficacy of Daptomycin for Injection in the treatment of patients with *S. aureus* bacteremia was demonstrated in a randomized, controlled, multinational, multicenter, open-label trial. In this trial, adult patients with at least one positive blood culture for *S. aureus* obtained within 2 calendar days prior to the first dose of study drug and irrespective of source were enrolled and randomized to either Daptomycin for Injection (6 mg/kg IV q24h) or standard of care (an anti-staphylococcal semi-synthetic penicillin 2 g IV q4h [nafcillin, oxacillin, cloxacillin, or flucloxacillin] or vancomycin 1 g IV q12h, each with initial gentamicin 1 mg/kg IV every 8 hours for first 4 days). Of the patients in the comparator group, 93% received initial gentamicin for a median of 4 days, compared with 1 patient (<1%) in the Daptomycin for Injection group. Patients with prosthetic heart valves, intravascular foreign material that was not planned for removal within 4 days after the first dose of

study medication, severe neutropenia, known osteomyelitis, polymicrobial bloodstream infections, creatinine clearance <30 mL/min, and pneumonia were excluded.

Upon entry, patients were classified for likelihood of endocarditis using the modified Duke criteria (Possible, Definite, or Not Endocarditis). Echocardiography, including a transesophageal echocardiogram (TEE), was performed within 5 days following study enrollment. The choice of comparator agent was based on the oxacillin susceptibility of the *S. aureus* isolate. The duration of study treatment was based on the investigator's clinical diagnosis. Final diagnoses and outcome assessments at Test of Cure (6 weeks after the last treatment dose) were made by a treatment-blinded Adjudication Committee, using protocol-specified clinical definitions and a composite primary efficacy endpoint (clinical and microbiological success) at the Test of Cure visit.

A total of 246 patients ≥18 years of age (124 Daptomycin for Injection, 122 comparator) with *S. aureus* bacteremia were randomized from 48 centers in the US and Europe. In the ITT population, 120 patients received Daptomycin for Injection and 115 received comparator (62 received an anti-staphylococcal semi-synthetic penicillin and 53 received vancomycin). Thirty-five patients treated with an anti-staphylococcal semi-synthetic penicillin received vancomycin initially for 1 to 3 days, pending final susceptibility results for the *S. aureus* isolates. The median age among the 235 patients in the ITT population was 53 years (range 21 to 91 years); 30/120 (25%) in the Daptomycin for Injection group and 37/115 (32%) in the comparator group were ≥65 years of age. Of the 235 ITT patients, there were 141 (60%) males and 156 (66%) Caucasians across the two treatment groups. In addition, 176 (75%) of the ITT population had systemic inflammatory response syndrome (SIRS) at baseline and 85 (36%) had surgical procedures within 30 days prior to onset of the *S. aureus</*
